**Nandar Hlaing, Pablo G. Morato
Philippe Rigo**

TO DO: Compute the lifetime fatigue damage at the indicated hotspot of NREL 5MW monopile wind turbine.

Geometry of monopile

Outer diameter of monopile = 6 m

Thickness of monopile = 60 mm

Design lifetime = 20 years

- 100 Simulation files including
 - 10-min recording of reaction force and moments at the mudline (M_{xx} , M_{yy} , F_{zz}) (Units – N, Nm)
 - Sampling frequency is 50 Hz (i.e., 30000 data points for 10 mins)
 - 10-min mean value of environmental and operational conditions (loadcase)
- Probability of occurrence of each 10-min loadcase

Calculation of nominal stress in time series

$$\sigma = -\frac{M_{xx} * r}{I} - \frac{F_{zz}}{A}$$

Rainflow Counting

- Given Matlab function: `my_rainflow` (same syntax as `rainflow`)
- 'Number of edges' and 'binWidth' can be adjusted (line 287-288)

Stress in time series and histogram

[C,hist,edges] = my_rainflow(**Sigma**,f) or my_rainflow(**Sigma**,t)

Table C (Exact)

cycles	range	mean	start	end
1	0.773			
1	0.221			
0.5	3.994			
1	5.676			
1	0.478			
1	2.111			
0.5	4.115			
1	1.162			
1	6.284			
1	4.123			
1	2.179			

Hist, edges (Approximate)

hist	edges
3	0
1	1
2	2
0.5	3
1.5	4
1	5
1	6
	7

$$m_1 = 3$$

$$m_2 = 5$$

$$\log_{10} a_1 = 12.164$$

$$\log_{10} a_2 = 15.606$$

$$\Delta\sigma \text{ (at knuckle point)} = 52.63$$

1. Using the S-N curve provided, calculate the short term 10-min damage for each loadcase.
2. Extrapolate to long term damage for 20 years taking into account the probability of occurrence.
